Assignment Project Exam Help

- A program is an expression (like an arithmetic expression) rather than a sequence of instructions

- All a program does is to

<https://eduassistpro.github.io/>

- ▶ There are no “side effects” — the only purpose of the program is to return a value

Add WeChat edu_assist_pro

- ▶ In a programming language based on the λ -calculus, there should be an instruction to the operating system (e.g. to write to a file, or to print to the screen)

Untyped (or "Type-Free") Lambda Calculus Syntax

program :: expression

expression :: x
 | expression e

- **Variable** : the name x
- **Application** : when one expression follows another, the former is the function and the latter is taken to be the argument, thus $expression_1$ applied to the argument $expression_2$
- **Abstraction** : the lambda abstraction $\lambda x.expression$ where x is the function name and $expression$ is the function body. The name x can be used inside $expression$ and represents the value to which the function is applied. We will assume that it is permissible for x to **not** appear inside $expression$ (there are different versions of the λ -calculus : some permit this, and some do not).

The type-free λ -calculus can compute anything that is computable. However, the minimal syntax is cumbersome. For example, the numbers 0 and 1 are represented as functions :

$$\begin{aligned} 0 &: \lambda f. \lambda x. x \\ 1 &: \lambda f. \lambda x. f x \end{aligned}$$

The syntax is therefore often extended with :

- Constant values such as
- Operators such as
 - ▶ Initially, all operators are binary
- Extra brackets for grouping
- Types (such as `char`, `bool`)
 - ▶ But we will not cover the typed lambda calculus¹
- Lambda abstractions with more than one argument : these can already be written as nested abstractions (e.g. $\lambda x. \lambda y. expression$ or $\lambda x. (\lambda y. expression)$) extended to permit the equivalent $\lambda x_1 x_2. expression$ or in general $\lambda x_1 \dots x_n. expression$

1. Note that whilst the untyped λ -calculus is Turing-equivalent, the typed λ -calculus typically is not (it depends on the properties of the type system)

Lambda calculus functions

Assignment Project Exam Help

- Functions do NOT have names!

- ▶ Functions can

- Function arguments

- ▶ that can only be used

- Functions can be arguments to other functions (they are

- ▶ that way they can have names when they are passed as arguments to other functions

- ▶ and can be used zero or more times inside the other function

- ▶ and it is also possible for a function to return a function as its result

<https://eduassistpro.github.io/>

Defining and applying a Lambda calculus function

- To define the (anonymous) function taking one argument (the argument is called x) which adds 1 to x and returns the sum as its result :

- Often simplified to $\lambda x. (x + 1)$ [but we must extend the synt

$\lambda x. (x + 1)$ [but we must extend the synt

- To apply the previously defined function to the constant number 3 :

$$(\lambda x. (x + 1)) 3$$

Untyped Lambda Calculus — extended syntax with infix operators

Rules for evaluation

- α -reduction

Assignment Project Exam Help

$$\lambda x.E \rightarrow \lambda y.E[y/x]$$

- β -reduction

- η -reduction

<https://eduassistpro.github.io/>

- δ -rules — there is a separate δ -rule for each operator (suc -rule for + says that $3 + 4$ evaluates to 7)

Add WeChat edu_assist_pro

- NB : $E[y/x]$ means “for each *free* occurrence of x in his becomes important if E contains another function definition that re-uses the name x for its argument. The embedded function definition *binds* the name x to a new value, thus the enclosing expression E sees all occurrences of x inside the embedded function definition as being *bound* (i.e. not *free*).

Terminology

Assignment Project Exam Help

- Binding — a BINDING links a name to a value. This happens whenever a function is applied.
- Bound and Not Bound

<https://eduassistpro.github.io/>

we say that x is BOUND and y is NOT BOUND (alternatively, y is FREE). This is because we know what value x refers to - it is the argument to the function. The value of y is unknown (presumably this expression occurs inside the function definition), but we don't know how deeply nested we might be inside function definitions.

Order of evaluation (“reduction order”)

Assignment Project Exam Help

- Normal Order Reduction

- ▶ “leftmost-o
- ▶ guaranteed t

- Other possible red

- ▶ applicative or
- ▶ parallel reduction

<https://eduassistpro.github.io/>

Add WeChat edu_assist_pro

All evaluation strategies are guaranteed to give the same result for an expression.
That unique result is called the **Normal Form** of the expression.

Lambda Calculus Examples

Example 1: **Assignment Project Exam Help**
 $(5 + 3) \rightarrow \text{by } \delta \text{ rule for } +$
 8

Example 2 : **<https://eduassistpro.github.io/>**
 $(\lambda x. (x + 3)) 5$
 $(5 + 3)$
 8

Example 3 : **Add WeChat edu_assist_pro**
 $(\lambda y. ((\lambda x. (x + y)) 5)) 3 \rightarrow \text{by } \beta \text{ reduction}$
 $(\lambda x. (x + 3)) 5 \rightarrow \text{by } \beta \text{ reduction}$
 $(5 + 3) \rightarrow \text{by } \delta \text{ rule for } +$
 8

Lambda Calculus Examples

Assignment Project Exam Help

Example 4 :

$(\lambda x.((\lambda x.(x + 3)) x)) 5 \rightarrow \text{by } \alpha \text{ reduction}$

$(\lambda y.((\lambda x.(x + 3)$

$(\lambda x.(x + 3)) 5$

$(5 + 3)$
